

32V/8A Ideal Diode Protection Switch

1 General Description

The RT1987 provides an ideal diode reverse current blocking function with low forward voltage and an enable input for disconnection. The 3.4V to 32V input operating range and 8A continuous current rating make the RT1987 well suited for multi-port USB-C sink current applications. In addition, this part includes a 40V Absolute Maximum Rating (AMR), a 20A peak current rating (up to 10ms), undervoltage-lockout, overvoltage protection, and over-temperature protection.

An adjustable soft-start circuit sets the output voltage slew rate and manages inrush current into high capacitance loads. Short-circuit protection is provided during this period, while the integrated MOSFET provides a low forward voltage drop and high Safe Operating Area (SOA).

The RT1987 is available in a VDFN-12T1L 3x3 package and can operate over -40°C to 125°C junction temperature.

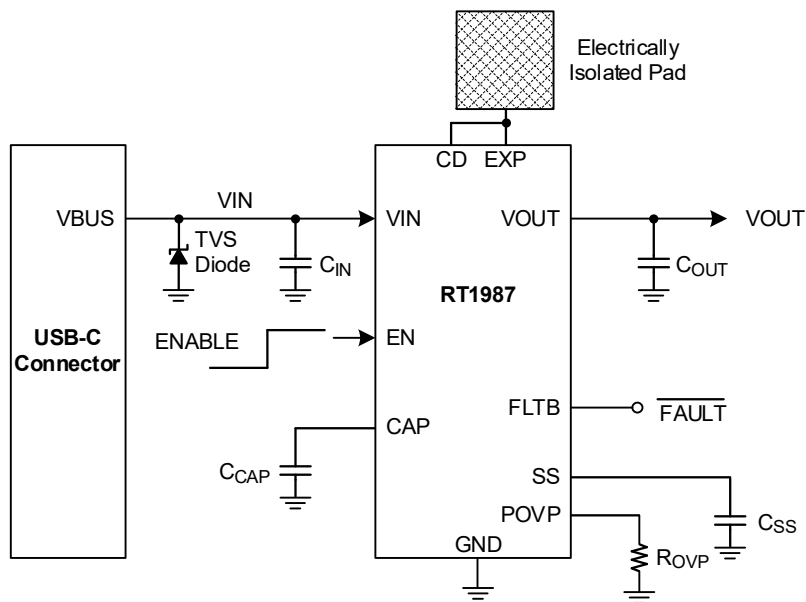

2 Features

- 8A Continuous/20A Peak Current Capability
- Input Supply Voltage: 3.4V to 32V
- 20mΩ (typical) Ron
- Analog Ideal Diode Gate Control
 - ▶ Blocks Reverse Current
 - ▶ Avoids Switch Chatter
 - ▶ Enables Fast Power Swap
- Programmable Soft-Start
- Programmable Overvoltage Protection
- Over-Temperature Protection
- Start-Up Short-Circuit Protection
- Compliance with IEC 61000-4-2 and IEC 61000-4-5 Standards

3 Applications

- USB-C/Thunderbolt Sink Power Delivery
- Docking Stations
- Power ORing Applications

4 Simplified Application Circuit

7 Pin Configuration

8 Functional Pin Description

Pin No.	Pin Name	Pin Function
1, 2	VOUT	Output voltage. Connect to load.
3	CAP	Connect a capacitor of 1nF to GND.
4	FLT B	Open-drain fault indicator. Connect a pull-up resistor to a low-voltage supply. This pin pulls low if a fault condition is detected.
5	EN	Enable active high. Pull high to enable ideal diode function. Pull low to disconnect VIN from VOUT.
6	GND	Ground.
7	SS	Soft-start input. Connect a capacitor, CSS, from SS to GND to set the soft-start time.
8	POVP	Programmable Overvoltage Protection threshold setting. Connect a resistor between this pin and GND or apply a direct DC voltage level for setting the OVP threshold.
9	CD	Common Drain node of the power switches. It must be electrically connected to Exposed pad.
10, 11, 12	VIN	Input voltage. Connect to a power input and bypass with a 10μF capacitor to GND.
13 (Exposed Pad)	EXP	Exposed pad. The exposed pad is electrically connected to the common-drain node of the internal power MOSFET and must be electrically isolated. For improved thermal performance, this pad should be soldered to a large electrically isolated pad and tied to as much copper (electrically isolated) as possible using many vias.

9 Functional Block Diagram

10 Absolute Maximum Ratings

(Note 2)

- VIN, VOUT, CD to GND----- -0.3V to +40V
- EN, SS, FLTB, POVP to GND----- -0.3V to +6V
- CAP to VIN ----- -0.3V to +12V
- CAP to GND ----- -0.3V to +46V
- IEC 61000-4-5 at VIN no CAP----- 45V
- Power Dissipation, PD @ TA = 25°C
 VDFN-12T1L 3x3----- 1.89W
- Package Thermal Resistance (Note 3)
 VDFN-12T1L 3x3, θ_{JA} ----- 53.05°C/W
 VDFN-12T1L 3x3, θ_{JC} ----- 5.22°C/W
- Lead Temperature (Soldering, 10 sec.)----- 260°C
- Junction Temperature ----- 150°C
- Storage Temperature Range ----- -65°C to 150°C

Note 2. Stresses beyond those listed under “Absolute Maximum Ratings” may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated in the operational sections of the specifications is not implied. Exposure to absolute maximum rating conditions may affect device reliability.

Note 3. θ_{JA} is measured under natural convection (still air) at TA = 25°C with the component mounted on a high effective-thermal-conductivity four-layer test board on a JEDEC 51-7 thermal measurement standard. θ_{JC} is measured at the bottom of the package.

11 ESD Ratings

(Note 4)

- HBM (Human Body Model) All Pins----- ±4kV
- IEC 61000-4-2 at VIN and VOUT----- ±8 kV

Note 4. Devices are ESD sensitive. Handling precautions are recommended.

12 Recommended Operating Conditions

(Note 5)

- Supply Input Voltage, VIN ----- 3.4V to 32V
- EN, FLTB ----- 0V to 5.5V
- CAP to VIN ----- 0V to 5.5V
- SS, POVP ----- 0V to 3V
- IVIN, IVOUT----- 0A to 8A
- Peak IVIN, IVOUT for 10ms at 2% Duty Cycle----- 20A
- Junction Temperature Range----- -40°C to 125°C

Note 5. The device is not guaranteed to function outside its operating conditions.

13 Electrical Characteristics

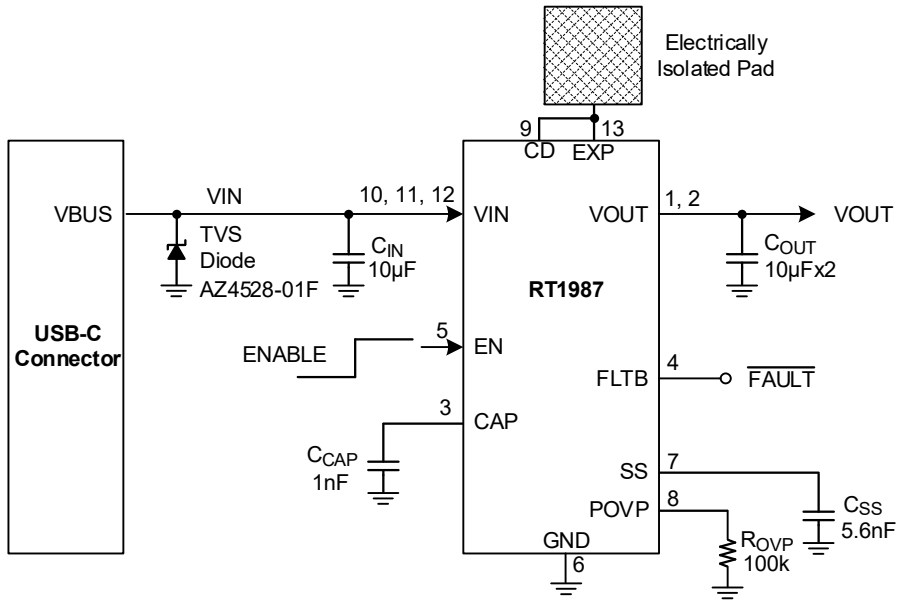

(TA = TJ = 25°C, VIN = 28V, VEN = 5V, CIN = 10μF, COUT = 10μF, CSS = 5.6nF, unless otherwise noted.)

Parameter	Symbol	Test Conditions	Min	Typ	Max	Unit

17 Operation

The RT1987 is a high-side protection device which is particularly well suited for USB-C sink applications. Its ideal diode functionality and back-to-back integrated 20mΩ MOSFETs provide reverse current blocking and diode-OR power source sharing while programmable soft-start, programmable overvoltage, over-temperature, and short-circuit protection features protect the system from faults. The 3.4 to 32V operating range aligns with USB-C voltage levels as well as other common power supplies. Unlike single MOSFET devices, the RT1987 completely isolates VIN and VOUT when disabled using the EN input.

17.1 Enable (EN and UVLO)

The active high EN pin provides on/off control for the power path while the input undervoltage lockout (UVLO) circuit monitors the input voltage (VIN). When VIN > VIN_UVLO (typically 3.175V), driving EN above VEN_R (1.4V max) turns on the power path. The timing diagram is shown in [Figure 1](#). Assuming no other faults – such as OVP or OTP – VOUT will start to ramp after tD_ON (typically 8ms). VOUT ramps up to VIN with a 10% to 90% rise time of approximately tON as set by CSS. See the [Soft-Start Slew Rate Control](#) section for more information.

Driving EN below VEN_F (0.6Vmin) disables the power path and puts the RT1987 in a low quiescent current state, drawing just ISHDN (typically 75µA). A low input voltage (VIN < VIN_UVLO – VUVLO_HYS, typically 2.925V) also disables the power path.

17.2 Power Delivery and Soft-Start

When an input voltage is first applied to the RT1987, the voltage at VOUT ramps up linearly with a slope determined by the SS pin capacitance. During this time, which is typically a few milliseconds, the RT1987 has high internal MOSFET stress with a power dissipation equal to (VIN – VOUT) x IOUT, where IOUT is the sum of the system load current and the current required to charge the output capacitance. The internal power dissipation is calculated as follows:

$$\text{Power} = (V_{IN} - V_{OUT}) \times I_{OUT} = (V_{IN} - V_{OUT}) \times \left(I_{SYS} + \frac{dV_{OUT}}{dt} \times C_{OUT} \right)$$

Where ISYS is the system load current and COUT is the output capacitance. The internal MOSFET ability to survive this high-power scenario depends on the FET safe operating area (SOA) as well as the thermal performance of the package – with a soft-start time of just a few milliseconds, the thermal performance of the PCB does not play a significant role. Refer to the [Application Information](#) section for example calculations and SOA curves to help determine an appropriate soft-start time for a given application.

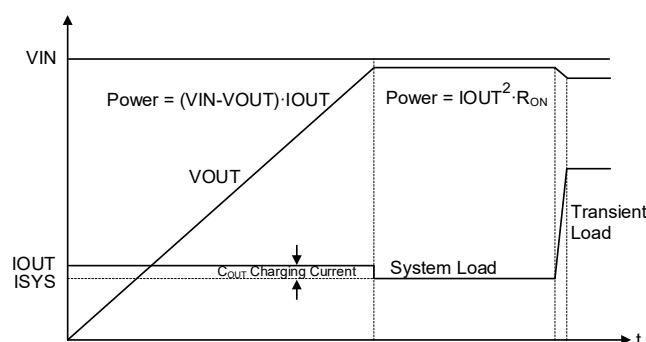

Figure 3. Soft-Start Power Dissipation

When the soft-start ramp is complete, the internal power device switches completely on (provided $ISYS \times R_{ON} > V_{FWD}$) and acts like a resistor with resistance R_{ON} . Because of the low differential voltage between V_{IN} and V_{OUT} , the power dissipation during this mode is considerably lower than during soft-start. Careful PCB layout consideration of thermal performance, combined with the low on-resistance of the internal power device, will ensure maximum system efficiency and minimal heat generation.

17.3 Soft-Start Slew Rate Control

When the RT1987 is first enabled, the soft-start function limits the rate of rise on the internal gate of the power device to control the V_{OUT} ramp and limit in-rush current. An external capacitor, C_{SS} , on the SS pin programs the 10% to 90% ramp time, t_{ON} , as follows:

$$t_{ON} = \frac{V_{IN}}{35} \times \left(\frac{C_{SS}}{0.0023} - 100 \right)$$

With C_{SS} in nF and t_{ON} in μs . To calculate C_{SS} :

$$C_{SS} = \frac{t_{ON}}{12.4 \times V_{IN}} + 0.23$$

17.4 Fault Protection

The RT1987 provides protection against reverse current (TRCB), overvoltage (OVP), overtemperature (OTP), and short-circuit (OCP) faults. When the device is first enabled, if any of the following conditions exist, the internal power MOSFET will not turn on:

1. $V_{IN} - V_{OUT} < V_{FRC}$ (typically -50mV)
2. $V_{IN} > V_{OVP_R}$ (33V when $POVP < 1.25V$; 23V when $POVP > 1.4V$)
3. $T_{DIE} > T_{OTP}$ (typically 140°C)

In addition, for conditions #2 (OVP), the FLTB pin will be pulled low to indicate the fault status of the device. Note that a TRCB condition prevents the power device from turning on but does not result in a fault indication. The RT1987 continuously monitors these conditions to determine when to allow the power path to be enabled. See [Table 1](#) for more information.

Table 1. Fault Response to Protection Features

Protection	Fault Response	FLTB Status
Reverse Current (TRCB)	Auto-restart without soft-start at fault removal	High Impedance
Overvoltage Protection (OVP)	Auto-restart with soft-start at fault removal	Low
Over-Temperature Protection (OTP)	Auto-restart with soft-start at fault removal	Low
Start-Up Short-Circuit Protection (SCP)	Auto-restart after t_{SCP_RST} (typically 64 ms)	Low

17.5 Start-Up Short-Circuit Protection (SCP)

During the soft-start ramp (t_{ON}), the RT1987 monitors for short-circuit faults. If the output current, I_{OUT} , exceeds I_{SCP} during the soft-start ramp, the internal MOSFET will turn off. To maximize the power handling capability of the internal MOSFET within SOA, I_{SCP} varies with $V_{IN} - V_{OUT}$. When the output voltage begins to start up, the initial value of the current limit is 2.5A. As the output voltage rises above 2V, the current limit starts to increase, with its value inversely proportional to $V_{IN} - V_{OUT}$, as shown in [Figure 4](#). A fixed timer is set to disable the power path if the inrush current is continuously clamped by the short-circuit current limit for 250 μs . The timer resets if the in-rush current drops below the current limit. In the case of an output short-circuit, the RT1987 will disable the power path by turning off the internal MOSFET when the 250 μs timer elapses. After t_{SCP_RST} (typically 64ms), the

auto-retry mode will enable the power path and try to start up again. Both the SCP current limit and shutdown functions are disabled after t_{ON} (when the soft-start completes and the internal MOSFET is fully enhanced). Large output capacitors may require a longer soft-start time.

Figure 4. Short-Circuit Protection

17.6 Ideal Diode True Reverse Current Blocking (TRCB)

When the power path is enabled, the ideal diode control circuitry attempts to regulate $V_{IN} - V_{OUT} = V_{FWD}$ (typically 35 mV). Provided that $I_{OUT} \times R_{ON} < V_{FWD}$, the drive circuitry servos the internal gate drive to maintain this differential voltage. If the load current increases such that $I_{OUT} \times R_{ON} > V_{FWD}$, then the internal MOSFET is fully enhanced, and the V_{IN} to V_{OUT} voltage is determined by the load current and R_{ON} . If V_{IN} decreases (or V_{OUT} increases) such that $V_{IN} - V_{OUT}$ falls to less than V_{FWD} , the ideal diode gate drive will force the internal MOSFET off. The ideal diode control circuitry is designed to accommodate relatively slow changes in load conditions. In the case of a fast transient, the RT1987 includes a fast reverse current comparator that trips within t_{FRC} (typically about 0.5 μ s) if $V_{IN} - V_{OUT}$ falls below V_{FRC} (typically - 50mV).

17.7 Programmable Overvoltage Protection (POVP)

The OVP circuit monitors the input voltage (V_{IN}) for an overvoltage event to protect downstream loads. The OVP threshold can be set by connecting a resistor between the POVP pin and GND or applying a direct DC voltage level to the POVP pin. When EN goes high and prior to the soft-start process, the OVP threshold setting will be latched. The OVP threshold remains unaffected by any subsequent changes. See [Table 2](#) for the OVP threshold setting.

When the RT1987 detects an overvoltage event, the resulting behavior depends on the current state of the power path. If the power path is on, the internal power device will be switched off after the OVP blanking time (t_{BLK_OVP} - typically 512 μ s). If the power path is off, OVP will prevent the internal power device from being turned on. In both cases, the FLTB pin is pulled low, indicating a fault condition. The RT1987 can be re-enabled by toggling the EN pin or cycling the input power supply.

Table 2. Overvoltage Protection Threshold Setting

POVP Voltage	OVP Threshold (Min.)
POVP < 1.25 V	33V
POVP > 1.4 V	23V

17.8 Over-Temperature Protection (OTP)

If the RT1987 die temperature reaches 140°C, the power path is disabled. Toggle the EN pin or cycle the input power to re-enable the part.

18 Application Information

(Note 7)

18.1 Input Capacitor Selection

A quality input capacitor provides a low impedance at high frequency to reduce input voltage transients, supply fast load transients, and reduce high-frequency noise. A 10 μ F ceramic input capacitor is recommended and should be placed as close to the VIN and GND pins as possible.

18.2 Output Capacitor Selection

While the RT1987 does not require a specific amount of output capacitance, the user should choose enough low ESR output capacitance to minimize high-frequency output voltage transients due to dynamic loads.

18.3 Thermal Considerations

The junction temperature should never exceed the absolute maximum junction temperature $T_{J(MAX)}$, listed under Absolute Maximum Ratings, to avoid permanent damage to the device. The maximum allowable power dissipation depends on the thermal resistance of the IC package, the PCB layout, the rate of surrounding airflow, and the difference between the junction and ambient temperatures. The maximum power dissipation can be calculated using the following formula:

$$P_{D(MAX)} = (T_{J(MAX)} - T_A) / \theta_{JA}$$

where $T_{J(MAX)}$ is the maximum junction temperature, T_A is the ambient temperature, and θ_{JA} is the junction-to-ambient thermal resistance.

For continuous operation, the maximum operating junction temperature indicated under Recommended Operating Conditions is 125°C. The junction-to-ambient thermal resistance, θ_{JA} , is highly package dependent. For a VDFN-12T1L 3x3 package, the thermal resistance, θ_{JA} , is 53.05°C/W on a standard JEDEC 51-7 high effective-thermal-conductivity four-layer test board. The maximum power dissipation at $T_A = 25^\circ\text{C}$ can be calculated as follows:

$$P_{D(MAX)} = (125^\circ\text{C} - 25^\circ\text{C}) / (53.05^\circ\text{C/W}) = 1.89\text{W for a VDFN-12T1L 3x3 package.}$$

The maximum power dissipation depends on the operating ambient temperature for the fixed $T_{J(MAX)}$ and the thermal resistance, θ_{JA} . The derating curve in [Figure 5](#) allows the designer to see the effect of rising ambient temperature on the maximum power dissipation.

Figure 5. Derating Curve of Maximum Power Dissipation
